Conclusion

Background: Unitary semantics

Unitary semantics of pure quantum computation

- An isolated **qubit** is a vector of norm 1 in \mathbb{C}^2 , with **basis** $|0\rangle = (1, 0)$ and $|1\rangle = (0, 1)$
- States composed of **n qubits** are vectors of norm 1 in the Hilbert space of the n -iterated tensor product

$$(\mathbb{C}^2)^{\otimes n} = \mathbb{C}^2 \otimes \cdots \otimes \mathbb{C}^2 = \mathbb{C}^{2^n}$$

with **computational basis states** $|i_1\rangle \otimes \cdots \otimes |i_n\rangle$

- Other states are linear combinations, in particular those that cannot be expressed as a n -ary tensor are **entangled**
- Pure operations are **unitary transformations** (linear and norm preserving) on that space

Quantum gates

- Basic operations are unitary transformations called **gates**
- They can be described by their **matrix representation**

Hadamard gate

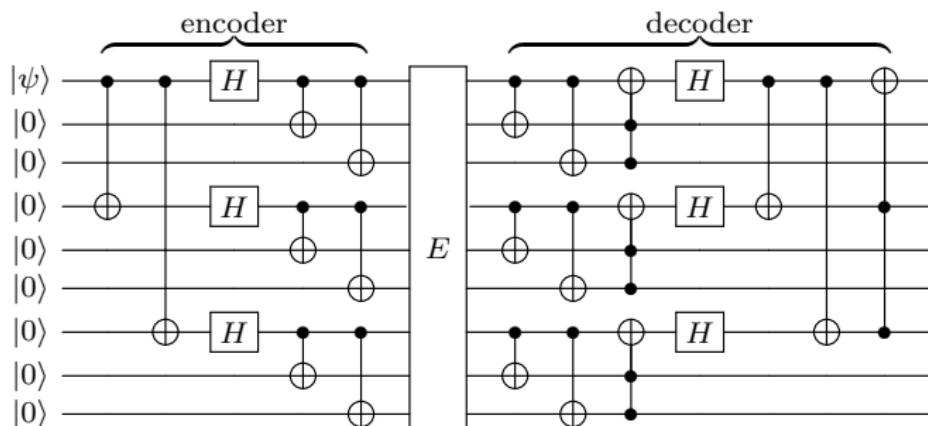

$$\boxed{H} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$$

CNOT gate

$$\begin{array}{c} \bullet \\ \oplus \end{array} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$$

Example of quantum circuit

Shor's 9-qubit code

- A quantum circuit applies unitary transformations to an input state to obtain an output state
- Here \boxed{E} denotes a possibly noisy quantum channel

Semantics of composition

- For pure computations, the whole circuit can also be described by a matrix
- Application of a gate to a large state uses **padding**, i.e. taking a tensor product with an **identity matrix** and **reordering** dimensions.

For instance the first CNOT gate becomes:

$$U_{2^{\otimes 9}}((42)) \begin{bmatrix} I_{128} & 0 & 0 & 0 \\ 0 & I_{128} & 0 & 0 \\ 0 & 0 & 0 & I_{128} \\ 0 & 0 & I_{128} & 0 \end{bmatrix} U_{2^{\otimes 9}}((24))$$

where $U_{2^{\otimes 9}}((24))$ is the tensor permutation matrix exchanging 2nd and 4th component of the tensor product

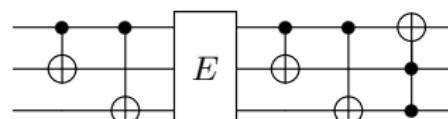

Problems with this semantics

- ① The size of matrices becomes huge (here 512×512)
- ② The reorderings are particularly cumbersome
- ③ While these problems can be fixed to some extent by using a [symbolic representation of Kronecker products](#), and/or by adopting the so-called [labelled Dirac notation](#), this comes at a cost in terms of compositionality

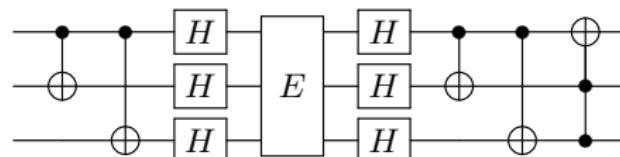

Compositionality

Shor's code is actually based on the following two simpler codes, which are able to fix respectively bit-flips and sign-flips.

Bit-flip code

Sign-flip code

We would like to be able to handle such **subcircuits** just like **gates**, but we do not want to be bothered by the permutations.

Quantum states as functions

An alternative view of quantum states

- uses the isomorphism $\mathbb{C}^2 \cong \{0, 1\} \rightarrow \mathbb{C}$
- The basis states $|0\rangle = (1, 0)$ and $|1\rangle = (0, 1)$ become

$$\begin{aligned}|0\rangle &= \lambda x : 2. \text{if } x = 0 \text{ then } 1 \text{ else } 0 \\|1\rangle &= \lambda x : 2. \text{if } x = 1 \text{ then } 1 \text{ else } 0\end{aligned}$$

where $2 = \{0, 1\}$

- This extends to states composed of n qubits:

$$\begin{aligned}\text{qustate}_n &= \{0, 1\}^n \rightarrow \mathbb{C} \\|i_1, \dots, i_n\rangle &= \lambda x : 2^n. \\&\quad \text{if } x = (i_1, \dots, i_n) \text{ then } 1 \text{ else } 0\end{aligned}$$

This looks like probabilistic programming

Generalization : Direct Power

For any vector space T , we define the direct power vector space of functions from the n th power of a finite type (e.g. 2^n) to T .

We use mathematical definitions from MATHCOMP.

direct power vector space

Variables ($I : \text{finite type}$) ($dI : I$) ($K : \text{field}$) .

Definition $d\text{power } n T := I^n \xrightarrow{\text{fin}} T$.

Notation $T^{\widehat{n}} := (d\text{power } n T)$.

Definition $d\text{pbasis } m (v_i : I^n) : (K^1)^{\widehat{m}} :=$
 $(v_j : I^n) \xrightarrow{\text{fin}} \text{if } v_i == v_j \text{ then } 1 \text{ else } 0$.

Definition $\text{morlin } m n := \forall T : \text{Vect}_K, T^{\widehat{m}} \xrightarrow{\text{lin}} T^{\widehat{n}}$.

This allows to nest quantum states without tensor product.

Generalization : Direct Power

For any vector space T , we define the direct power vector space of functions from the n th power of a finite type (e.g. 2^n) to T .

We use mathematical definitions from MATHCOMP.

direct power vector space

Variables ($I : \text{finite type}$) ($dI : I$) ($K : \text{field}$) .

Definition $d\text{power } n T := I^n \xrightarrow{\text{fin}} T$.

Notation $T^{\widehat{n}} := (d\text{power } n T)$.

Definition $d\text{pbasis } m (v_i : I^n) : (K^1)^{\widehat{m}} :=$
 $(v_j : I^n) \xrightarrow{\text{fin}} \text{if } v_i == v_j \text{ then } 1 \text{ else } 0$.

Definition $\text{morlin } m n := \forall T : \text{Vect}_K, T^{\widehat{m}} \xrightarrow{\text{lin}} T^{\widehat{n}}$.

This allows to nest quantum states without tensor product.

Problem: how do we ensure that functions in $\text{morlin } m n$ have a unique matrix representation, that does not depend on T ?

Naturality

The solution is to additionally require naturality.

naturality

$$\begin{array}{ccc}
 T_1 & T_1^{I^m} & \xrightarrow{G_{T_1}} T_1^{I^m} \\
 \varphi \downarrow & \varphi^{I^m} \downarrow & \downarrow \varphi^{I^m} \\
 T_2 & T_2^{I^m} & \xrightarrow{G_{T_2}} T_2^{I^m}
 \end{array}$$

Definition $\text{dpmap } m\ T_1\ T_2\ (\varphi : T_1 \rightarrow T_2)\ (\text{st} : T_1^{\widehat{m}}) : T_2^{\widehat{m}} :=$
 $(v : I^m) \xrightarrow{\text{fin}} \varphi(\text{st}(v)).$ (($\text{dpmap } \varphi$) is denoted φ^{I^m} above)

Definition $\text{naturality } m\ n\ (G : \text{morlin } m\ n) :=$
 $\forall(T_1\ T_2 : \text{Vect}_K), \forall(\varphi : T_1 \xrightarrow{\text{lin}} T_2),$
 $(\text{dpmap } \varphi) \circ (G\ T_1) = (G\ T_2) \circ (\text{dpmap } \varphi).$

Linearity, naturality, unitarity

(* natural morphisms *)

Record mor m n := { $\varphi : \text{morlin } m n \mid \text{naturality } \varphi$ }.

Notation endo n := (mor n n).

(* from matrix *)

Definition tsmor n m : $(K^{\widehat{m}})^{\widehat{n}} \rightarrow \text{mor } m n$.

(* vertical composition *)

Definition comp_mor : mor m p \rightarrow mor n m \rightarrow mor n p.

Notation "F \v G" := (comp_mor F G).

(* unitarity *)

Definition unitary_endo m n (F : mor m n) :=

$\forall s t, \text{tinner } (F K^1 s) (F K^1 t) = \text{tinner } s t$.

(K^1 is the field K seen as a vector space)

Representing Shor's code

```
Notation tsapp l M := (focus l (tsmor M)).
```

```
Definition bit_flip_enc : endo 3 :=
  tsapp [lens 0; 2] cnot \v tsapp [lens 0; 1] cnot.
```

```
Definition bit_flip_dec : endo 3 :=
  tsapp [lens 1; 2; 0] toffoli \v bit_flip_enc.
```

```
Definition hadamard3 : endo 3 :=
  tsapp [lens 2] hadamard \v tsapp [lens 1] hadamard
  \v tsapp [lens 0] hadamard.
```

```
Definition sign_flip_dec := bit_flip_dec \v hadamard3.
```

```
Definition sign_flip_enc := hadamard3 \v bit_flip_enc.
```

```
Definition shor_enc : endo 9 :=
  focus [lens 0; 1; 2] bit_flip_enc \v
  focus [lens 3; 4; 5] bit_flip_enc \v
  focus [lens 6; 7; 8] bit_flip_enc \v
  focus [lens 0; 3; 6] sign_flip_enc.
```

```
Definition shor_dec : endo 9 := ...
```

Proving Shor's code

We have only proved the correctness for error-free channels.

```
Definition flip (i : 'I_2) := rev_ord i. (* exchanges 0 and 1 *)
Lemma tsmor_cnot0 i : tsmor cnot Co {|0, i} = {|0, i}.
Lemma tsmor_cnot1 i : tsmor cnot Co {|1, i} = {|1, flip i}.
Lemma tsmor_toffoli00 i : tsmor toffoli Co {|0,0,i} = {|0,0,i}.
Lemma hadamardK T : involutive (tsmor hadamard T).

Lemma bit_flip_enc0 j k : bit_flip_enc Co {|0,j,k} = {|0,j,k}.
Lemma bit_flip_enc1 j k :
  bit_flip_enc Co {|1,j,k} = {|1, flip j, flip k}.

Lemma bit_flip_toffoli :
  (bit_flip_dec \v bit_flip_enc) = tsapp [lens 1; 2; 0] toffoli.
Lemma sign_flip_toffoli :
  (sign_flip_dec \v sign_flip_enc) = tsapp [lens 1; 2; 0] toffoli.

Theorem shor_code_id i :
  (shor_dec \v shor_enc) Co {|i,0,0,0,0,0,0,0,0} = {|i,0,0,0,0,0,0,0,0}.
```

The above lemmas require about 80 lines of proof in total.

Focusing in and out

We provide a number of functions and lemmas that allow to change the view of the current state.

Variables $(n \ m : \text{nat}) \ (l : \text{lens } n \ m)$.

Definition $\text{dpmerge} : (K^1)^{\widehat{n}} \rightarrow (K^1)^{\widehat{m}} \xrightarrow{\text{lin}} (K^1)^{\widehat{n}}$.

Lemma $\text{focus_dpbasis} \ (f : \text{endo } n) \ (vi : I^n) :$
 $\text{focus } l \ f _ \ (\text{dpbasis } vi) =$
 $\text{dpmerge } vi \ (f _ \ (\text{dpbasis } (\text{extract } l \ vi)))$.

Lemma $\text{dpmerge_dpbasis} \ (vi : I^n) \ (vj : I^m) :$
 $\text{dpmerge } vi \ (\text{dpbasis } vj) =$
 $\text{dpbasis } (\text{merge } l \ vj \ (\text{extract } (\text{lensC } l) \ vi))$.

Lemma $\text{decompose_scaler} \ k \ (st : (K^1)^{\widehat{n}}) :$
 $st = \sum_{t:I^k} st \ t *: \text{dpbasis } t$.

Conclusion

We have provided an alternative account of pure quantum computation, based on

- quantum state seen as function
- currying of this function for focusing
- parametric polymorphic definition of transformations
- characterizing parametricity by naturality

This approach allowed us to prove a number of pure circuits

- Shor's 9-qubit code (on error-free channel)
- GHZ state preparation
- reverse circuit

The ability to manipulate state through currying really seems to simplify proofs!
