In this problem we consider games like tic-tac-toe or gomoku-narabe, but for simplicity we have only one dimension (all points are aligned).

1. Linear tic-tac-toe

In this game, we play on the integer line \mathbf{Z} . Two players, an attacker and a defender, take positions (integers) in turn. A position can be taken only once, and by one player. The attacker plays first. The attacker wins if she can take 3 consecutive positions (*i.e.* x , $x + 1$, and $x + 2$). The defender succeeds if she has a strategy such that the attacker can never win.

- a. Prove that the defender has a successful strategy.

2. Arithmetic tic-tac-toe

In this game, we play on the integer line \mathbf{Z} . Two players, an attacker and a defender, take positions (integers) in turn. A position can be taken only once, and by one player. The attacker plays first. The attacker wins if she can take n equidistant positions (*i.e.* x , $x + d$, $x + 2d$, \dots , $x + (n - 1)d$ for some $d > 0$). The defender succeeds if she has a strategy such that the attacker can never win.

- a. Prove that for $n = 3$ and $n = 4$, an attacker can win against any defender.
- b. Prove it also for $n = 5$ (we conjecture this is true).
- c. For $n > 6$, try to provide a proof of whether the attacker or the defender have a successful strategy.

Note For arithmetic tic-tac-toe, you may use the rational line \mathbf{Q} instead of \mathbf{Z} . They are equivalent for finite games.
